RII Track-2 FEC: Developmental Chronnecto-Genomics (Dev-CoG): \$1,500,000/year
A Next Generation Framework for Quantifying Brain Dynamics and
Related Genetic Factors in Childhood

The rapid development of the brain's network architecture during childhood provides an unprecedented opportunity to gain a more complete understanding of the role of oscillatory behavior and network connectivity in normal brain functioning and cognitive development. New Mexico, Nebraska, and Louisiana envision a consortium on developmental chronnecto-genomics (Dev-CoG) whose overarching goal is to advance understanding of child-hood brain connectivity by developing new analytic approaches to study connectivity over brief and extended periods of time (the chronnectome), via multiple neuroimaging modalities, and in turn determine how their genetic underpinnings further influence this developmental trajectory.

Unified multivariate data-driven solutions for static and dynamic brain connectivity \$450,000/year

There is considerable interest in approaches that capture time-varying connectivity, however existing approaches are largely ad-hoc and hard to compare with one another. Existing approaches have shown considerable promise, but no method currently provides a comprehensive view of the time-varying changes we know exist. For example, most studies focus on time-varying correlation but ignore time-varying nodes. Most approaches produce state matrices, but it's not clear how to relate these or even if they are meaningful. Multivariate methods are well suited to estimate the changes of interested in a unified and robust manner but such tools are still in their infancy. We thus propose to develop and validate a family of multivariate methods to estimate dynamic connectivity states (CS) and use these methods to study CS in overlapping psychosis patients (schizophrenia/bipolar disorder) and comorbid conditions (smoking/drinking). Our tools have wide application to the study of the healthy brain as well as many other diseases such as Alzheimer's and attention deficit hyperactivity disorder.

Mining the Genomewide Scan: Genetic Profiles of Structural Loss in Schizophrenia \$600,000/year
The development of both neuroimaging and genome-wide scan technologies have created a proliferation of data about neuropsychiatric disorders. It is possible to collect more information in a study about each subject than there are subjects available to study, creating a challenge for standard statistical techniques. We develop an approach already used separately in imaging and genetics, but apply it here to the combination of imaging genetic data on a massive dataset, to determine genetic effects on brain structure in psychiatric disorders.

Integrative analysis of imaging, genomics, and epigenomics data \$480,000/year

Integration of fMRI imaging, genomics, network and biological knowledge \$400,000/year
We will integrate imaging and genomics including interacting patterns. We will challenge the current paradigm of integrative data analysis, which fails to consider the specific characteristics of multiple modal data (e.g., correlations between multiple datasets, availability of limited small size of samples). With our solid background and strong experience in statistics, bioinformatics, genetics, and clinical genomics research, we are able to develop an interdisciplinary approach that combines computational innovations such as sparse representations with latest genomic imaging techniques for mental illness diagnosis. .

We will apply these techniques to the analysis of functional magnetic resonance (fMRI) data (both the magnitude and full complex fMRI data) and the rejection of gradient and pulse artifacts in electroencephalography (EEG) in concurrent EEG-fMRI data. MRI DNA Biomarkers for Neuropsychiatric Disease

There is an urgent need for innovative technologies to study the multi-gene etiology of these disorders for early diagnosis, prevention, and treatment. Advances in the Genomas PhysioGenomics™ technology allow us to develop disease related DNA arrays. These products will enable researchers to couple neuropsychiatric endophenotypes, structural and functional imaging of the brain) with genetic information from hundreds of genes, including single nucleotide polymorphisms (SNPs) and haplotypes, to build multigene DNA markers of disease.

A unified framework for flexible brain image analysis

\$350,000/year directs

The imaging findings in schizophrenia are widespread, heterogeneous, not diagnostic, and have limited replicability and it is likely that in part the lack of consistent findings is because most models do not adequately account for the variability present in the data from schizophrenia patients. The successful completion of this research will provide a powerful set of algorithms and software tools for the research community to increase the sensitivity and specificity of functional brain imaging techniques.

Genetic Markers of White Matter Integrity and Clinical Severity in Schizophrenia

\$320,000/year directs

The goal of this Challenge grant application is to identify novel biomarkers of clinical severity in patients with schizophrenia. There are currently no reliable biomarkers for schizophrenia, so the proposed use of sophisticated genotyping, neuroimaging and biostatistical tools for searching biomarkers that can predict disease severity in two large cohorts of patient has a high clinical impact. The identification of such biomarkers will not only increase our knowledge of the pathophysiology of schizophrenia but also, and most importantly, may help predict an increased risk for this illness even before the onset of symptoms.
